

The new conception on treatment effect of bloodletting therapy

In the result of conducting the experimental works in mice, had been confirmed our new conception relating to treatment effect of bloodletting therapy i.e, the mechanism of bloodletting therapy had appeared in the following forms such as “elimination of toxic lipid peroxidation products from membrane structures of immunocytes under bloodletting therapy - inhibition of apoptosis - increase of proliferation of immunocytes - the appearance of new generation of immunocytes - improve the biosynthesis of membrane - binding receptor and markers.”
